1. Introduction

1.1 Purpose and scope

Initia Ltd (Initia) was engaged by Greenstone Land Developments Ltd to provide geotechnical services in relation to the proposed residential subdivision at a site off Kenny Road, Te Awa, Napier. This report presents a summary of the works undertaken and provides relevant geotechnical recommendations for the proposed development. Initia were commissioned part way through the earthworks to provide certification of the site for residential housing.

An area within Lot 2 is currently being used to site a detention pond to manage stormwater run-off. This will be backfilled with similar engineered fill to remainder of Stage 2 at a later date. Initia will provide a letter report for the Lot 2 sign off when this work has been completed and the earthwork test results have been provided to us.

This report and subsequent recommendations only relate to Lots 3 to 24 (Stage 2).

The following works have been undertaken in accordance with our proposal dated 30 April 2020¹:

- A review of local geology (published geological maps).
- A site inspection by a geotechnical engineer.
- A review of historic investigations carried out by Resource Development Consultants Limited (RDCL)
- Site specific geotechnical investigations comprising:
 - 2 No. machine drilled boreholes to depths of between 13.05m and 15.37m below ground level (bgl);
 - 23 No. Cone Penetration Tests (CPT) to depths of between 11.02m and 13.92m bgl.
- An assessment of site subsoil class in accordance with NZS 1170.5:2004².
- An assessment of seismic hazard using CPT data.
- An assessment of geotechnical considerations associated with the foundation design.
- An assessment of geotechnical considerations associated with the pavement design.
- Preparation of this report.

1.2 Proposed Development

The proposed development comprises a 48-lot subdivision with an existing house being retained in the southern area of the site adjacent to Kenny Road (Lot 1). The majority of the site has been raised due to the Napier City Council (NCC) flood levels in the area. A retaining wall is to be constructed along the western boundary of the site with the retained height up to 1.2m. The Earthworks plan by Strata Group³ attached in Appendix A indicates up to 1.5m of engineered fill has been placed across the site.

Access to the subdivision is proposed to be via two roads, one off Kenny Road to the south of the site and from Waimakariri Drive to the north.

A Resource Consent (RMS19069) has already been granted for this project based on previous investigations from other consultants (RDCL).

¹ Initia Ltd (30 April 2020). Proposal for Geotechnical Consultancy Services – Kenny Rd Subdivision, Te Awa, Napier.

² New Zealand Standard (2004). Structural Design Actions – Earthquake Actions – New Zealand.

³ Strata Group Consulting Engineers Ltd (26 June 2019), Earthworks Plan – Te Awa, Kenny Road, Napier. Ref J5174.

2. Site Conditions and Geology

2.1 Site Description and Location

The site of interest (legally named Lot 2 DP 532863) is located off Kenny Road in Te Awa, Napier. The site is 540m west of the Napier coastline. The site was previously used as a lifestyle farming block and contains well established trees in the southern and eastern parts of the site. The site appears to be on a former flood plain and is therefore typically flat, sitting at an elevation of approximately RL 11m – 12m. The site is bounded by developed residential property to the north, east and west of the site, with Kenny Road to the south of the site. Refer to Figure 2-1 below:

Figure 2-1 - Site Overview with highlighted boundaries

We note there is a stormwater overland flow drain along the eastern boundary of the site that has been infilled as part of this development.

2.2 Geological setting

The geological Map of the Hawke's Bay Area⁴ shows the site to be underlain by Holocene aged Alluvial Deposits comprising gravel, sand and silt and clay, forming the Heretaunga Plains. Refer to Figure 2-2 below:

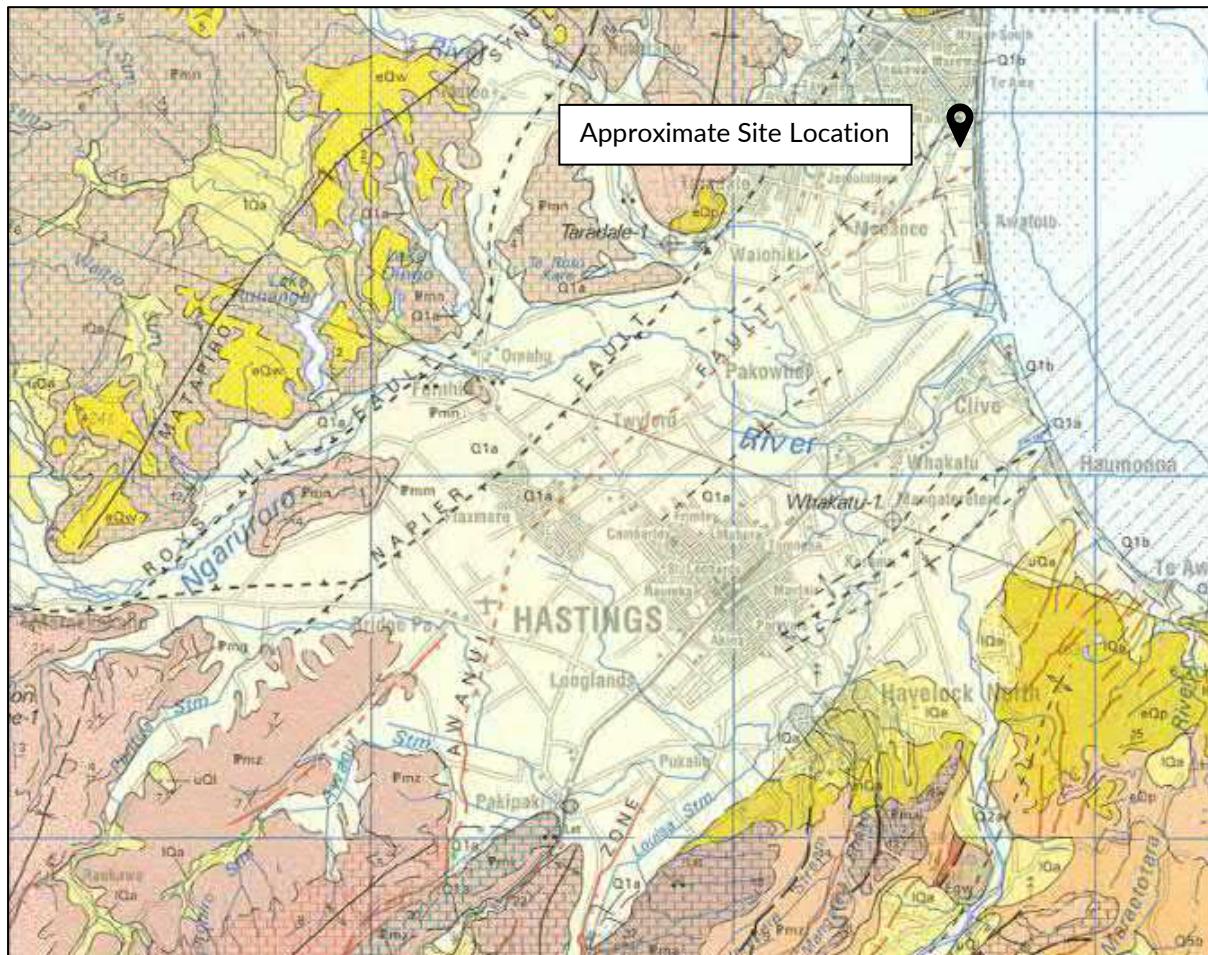

Figure 2-2 - Geological Map of the Hawkes Bay Area showing site area.

⁴ Lee, J.M.; Townsend, D.; Bland, K.; Kamp, P.J.J. (compilers) 2011: Geology of the Hawke's Bay area: scale 1:250,000. Lower Hutt: Institute of Geological & Nuclear Sciences Limited. Institute of Geological & Nuclear Sciences 1:250,000 geological map 8. 86 p. + 1 folded map

3. Geotechnical Investigations

3.1 Previous investigations (RDCL, 2019)

Resource Development Consultants Limited (RDCL) have previously carried out a site investigation comprising 8 No. Test Pits, 8 No. Dynamic Cone Penetrometers (DCP's) and 10 Cone Penetration Tests (CPT's) and produced a geotechnical report in July 2019. The DCP's were undertaken adjacent to the test pits. Refer to Table 3-1 below for the co-ordinates and depth of each test:

Table 3-1 - RDCL's site investigation

ID	Coordinates (NZTM) ¹		Depth (mbgl)
	Easting (m)	Northing (m)	
CPT01	1936382.6	5617594.6	10.34
CPT02	1936322.1	5617550.5	11.52
CPT03	1936283.9	5617592.0	12.48
CPT04	1936245.4	5617524.5	12.70
CPT05	1936275.9	5617476.4	12.34
CPT06	1936234.5	5617434.2	13.42
CPT07	1936309.6	5617431.9	12.46
CPT08	1936317.2	5617508.3	11.90
CPT09	1936381.1	5617508.3	10.70
CPT10	1936379.1	5617438.4	11.46
TP01	1936290.9	5617592.8	3.40
TP02	1936233.9	5617527.7	3.30
TP03	1936251.7	5617440.8	3.40
TP04	1936313.4	5617466.2	3.30
TP05	1936317.1	5617529.8	3.20
TP06	1936382.1	5617426.8	3.10
TP07	1936378.0	5617533.71	3.00
TP08	1936377.3	5617602.78	3.20

Note 1: Coordinate system – NZTM2000.

The existing investigation data indicates that the site is typically underlain by weak alluvial deposits comprising silts and sands, A dense gravel layer is identified at approximately 12m below ground level.

Some main findings of the RDCL report were:

- The site comprises loose unconsolidated alluvial deposits, highly susceptible to liquefaction.
- The site has a very high risk of liquefaction with vertical settlements of 300mm anticipated for a ULS event.
- The site is prone to flood levels for a 50-year return period. Earthworks may be required to elevate ground levels above flood levels.
- Foundations will require TC3 type in accordance with MBIE Part C Technical Guidance which in Hawkes Bay practically means a 1.2m undercut with the construction of a reinforced gravel raft.

Refer to Appendix B for the RDCL report and investigation logs.

3.2 Current investigation (Initia, 2020)

On 20 to 22 May 2020, a site investigation comprising 2 No. Machine Boreholes (BHs) and 23 No. Cone Penetration Tests (CPTs) was carried out by Geotech Drilling Ltd under the supervision of a Geotechnical Engineer from Initia. The boreholes were logged in accordance with the New Zealand Geotechnical Society (NZGS) 'Field description of Soil and Rock' guidelines. The recent Initia investigation plan and logs are attached in Appendix C. Refer to Table 3-2 below for the location coordinates and depth of each test:

Table 3-2 – Initia site investigations

CPT23	1936229.4	5617429.4	13.92

Note 1: Coordinate system – NZTM2000 (measured by handheld GPS).

3.3 Groundwater

The groundwater levels recorded at the machine boreholes after testing were 1.6m bgl at BH01 and 2.3m bgl at BH02. Groundwater depths across the site varied from site-specific locations typically ranging from 0.8m bgl – 3.4m bgl inferred from the CPT testing. This was measured during May 2020 (end of autumn) and ground water levels are expected to be shallower during wet winter months.

A piezometer standpipe was installed at BH01 to monitor the groundwater levels which are likely to be higher in the upcoming winter period.

3.4 Laboratory Testing

3.4.1 Sampling

Soil samples were extracted from the two boreholes during the investigation. 3 No. samples were taken from the site per borehole for testing.

3.4.2 Laboratory Test Scheduling

A total of 6 laboratory tests were chosen to be carried out from the two machine boreholes. These tests included:

- 6 No. Atterberg Limit tests to test the soils for their Liquid Limit, Plastic Limit and Plasticity Index.

This type of testing assists with the liquefaction classification for the soils at the site.

3.4.3 Laboratory Testing and Results

Geotechnical testing of soil samples was undertaken by Babbage Geotechnical Laboratory. The laboratory testing results is presented in Appendix D.

Testing was carried out in accordance with the following specifications:

- Atterberg Limits
ASTM D4318 - 10e1: Standard Test Methods for Liquid Limit, Plastic Limit, and Plasticity Index of Soils

4. Site stratigraphy

The results of the most recent geotechnical investigations carried by Initia (2020) indicates that the site is underlain by the following soil units:

- Unit 1: Firm sandy SILT and SAND with trace clayey lenses; overlying
- Unit 2: Soft silty CLAY and Clayey SILT; overlying
- Unit 3: Firm sandy SILT and SAND; overlying
- Unit 4: Soft silty CLAY and SILT; overlying
- Unit 5: Loose Silty SAND and SAND interbedded with soft to firm SILT/CLAY; overlying
- Unit 6: Soft Clayey SILT and Silty CLAY with some thin sandy lenses; overlying
- Unit 7: Dense Gravelly SAND to very dense GRAVEL

This geological sequence is typical of the Heretaunga Plains which comprise alluvial soils of the Holocene age, based on our previous experience. The nature and continuity of the subsoils away from the investigation locations is inferred and it must be appreciated that actual conditions may vary from the assumed model.

4.1.1 Unit 1: Firm sandy SILT and SAND with trace clayey lenses

The very upper soil unit of the site comprises Sandy SILT and SAND, at a thickness of 0.5m – 1.8m. The CPT measured cone tip resistance (q_c) was generally around 4MPa for this layer.

4.1.2 Unit 2: Soft silty CLAY and Clayey SILT

A layer of soft Silty CLAY Clayey SILT underlies the above layer, at a thickness of approximately 0.5m – 0.6m. The material within this layer is typically highly plastic and moist. The CPT measured cone tip resistance (q_c) was generally low, around 0.5-1MPa for this layer.

4.1.3 Unit 3: Firm sandy SILT and SAND

Below the upper silty clay and clayey silt layer lies a sandy SILT – SAND soil unit approximately 0.8-1.2m thick. This sand in this unit was generally fine to medium grained and was saturated. The CPT measured cone tip resistance (q_c) was generally around 2MPa for this layer.

4.1.4 Unit 4: Soft silty CLAY and SILT

A layer of soft Silty CLAY and SILT follows the upper layers with a thickness of 0.6-1.5m. The material within this layer is typically highly plastic and wet with some traces of shell fragments found throughout the layer. The CPT measured cone tip resistance (q_c) was generally low, around 0.5MPa for this layer.

4.1.5 Unit 5: Loose Silty SAND and SAND interbedded with soft to firm SILT/CLAY

The next soil unit was a silty SAND and SAND unit with interbedded layers of CLAY. This unit has a thickness of 4.0-8.5m. The SAND was generally fine to medium grained. The interbedded layers of cohesive material were generally high in plasticity with trace shell fragments. The CPT measured cone tip resistance (q_c) was generally around 4MPa for this layer.

4.1.6 Unit 6: Soft Clayey SILT and Silty CLAY with some thin sandy lenses

A layer of soft clayey SILT and silty CLAY follows the upper layers with a thickness of 1.6-3.2m. The soil unit was generally highly plastic, soft in nature and wet to saturated. The CPT measured cone tip resistance (q_c) was generally low, around 0.5MPa for this layer.

4.1.7 Unit 7: Dense Gravelly SAND to very dense GRAVEL

This unit is described as gravelly SAND and GRAVEL., Three Standard Penetration Tests (SPT) were performed in this layer with results being 40, 49 and 50+ indicating this layer is dense to very dense. The maximum depth of this soil unit was not proven during these investigations.

The presence of this dense to very dense GRAVEL layer is also evidenced by the recent CPTs which all recorded a significant increase in the cone resistance which resulted in refusal of penetration at similar depths to those identified in the boreholes.

A summary of the site stratigraphy, layer thicknesses and their measured in situ strength test results are presented in the table below:

Table 4-1 - Site Stratigraphy

Geological Unit	Soil description	Depth to top of unit (m)	Layer thickness range (m)	In situ test parameters – range and [typical values]		
				S _u (kPa)	q _c (MPa)	SPT 'N' value
Holocene Alluvium	Unit 1: Sandy SILT and SAND with trace clayey lenses	0.0	0.5-1.8	Not Proven	1-16 [4]	N/A
	Unit 2: Soft silty CLAY and Clayey SILT	0.5-1.8	0.5-0.6	Not Proven	0.5-1 [0.5]	N/A
	Unit 3: sandy SILT and SAND	1.0-2.4	0.8-1.2	N/A	1-6 [2]	N/A
	Unit 4: Soft silty CLAY and SILT	2.0-3.4	0.6-1.5	Not Proven	0.5-1 [0.5]	N/A
	Unit 5: Silty SAND and SAND interbedded with soft to firm SILT/CLAY (up to 2.0m thick layer)	3.0-4.8	4.0-8.5	N/A	0.5-16 [4]	N/A
	Unit 6: Soft Clayey SILT and Silty CLAY with some thin sandy lenses	8.0-11.8	1.6-3.2	Not Proven	0.5-1 [0.5]	N/A
	Unit 7: Dense to very dense gravelly SAND and GRAVEL	10.8-13.7	Not Proven	N/A	Not Proven	40-50+ [45]

5. Fill Certification

5.1 Earthworks

According to the Zorn Surveying fill contour plan, it appears 0.3m–1.5m of engineered fill has been placed across the site. This is essential to bring the level of the site to be above the NCC flood levels in the area.

The site was cleared of vegetation and any topsoil present stripped from the work area. Where practicable, disturbance to vegetation cover outside the extent of the earthworks has been minimised to aid sediment control.

Compaction of any fill material has been in accordance with NZS 4404:2010. The imported granular fill has been placed in 200mm maximum layer thicknesses and compacted to an engineered specification.

River silt was imported to the site for this project and the following preliminary compaction criteria for this material was recommended:

Compaction of Imported River Silt

Dry density – NDM:	Minimum Dry Density	92%
	Average Dry Density	95%

All material used as fill on site was reviewed by the Geotechnical Engineer prior to placement.

5.2 Testing Results

Initia have been provided with all the engineered fill test results that relate to all the lots across both Stage 1 and 2. Typically, all the testing indicated greater than 95% of Maximum Dry Density (MDD). In terms of strength of the engineered fill layer, there is a significant increase in strength shown in the CPT plots where the probe has been pushed through the engineered fill later at the surface.

Some high voids have been noted on the test data received by Initia. We understand that this was due to a delay in the earthworks testing following compaction in warmer summer months.

Copies of all the test data and relevant compaction curves are presented in Appendix D.

6. Geotechnical Considerations

6.1 General

The following geotechnical considerations are relevant to the design and construction of the proposed development and are addressed in the following sections:

- Site seismicity and subsoil class;
- Liquefaction assessment;
- Static Settlement risk;
- Retaining wall design parameters;
- Foundation Options

The interpretations, advice and recommendations presented in this report are based on geotechnical investigations completed by Initia and others at point locations. The nature and continuity of the ground conditions away from the investigation locations is inferred and it must be appreciated that actual conditions could vary from the assumed model.

6.2 Site seismicity and subsoil class

Based on the previous and recent geotechnical investigations at the site and in the adjacent area, we consider that the site subsoil class should be classified as Class D – Deep or Soft Soil Site, in accordance with NZS1170.5 (2004)⁵.

For determination of the design Peak Ground Acceleration (PGA), we have assumed an Importance Level 2 and a 50-year design life for the future structures likely to be situated across the subdivision development.

Table 6-1 Design PGA and average magnitude of an earthquake contributing to PGA

Limit States	Return Period	PGA	Average Magnitude
ULS	500 years	0.33g	6.9
SLS	25 years	0.08g	6.2

Note: The design PGAs have been based on an Importance Level 2 structure and a 50-year design life.

6.3 Liquefaction susceptibility & triggering

The liquefaction susceptibility of the underlying material at the proposed subdivision has been assessed using the results of the Initia 2020 Investigations.

A CPT-based liquefaction analysis has been carried out using the computer programme CLiq v.2.3⁶ on the recent Initia CPTs (23 No.). The adopted analysis method is based on the study by Boulanger and Idriss (2014).

There is a general agreement that sands, non-plastic silts, and gravels mixtures form soils that are susceptible to liquefaction. Based on the site investigation and the laboratory test results, two of the stratigraphic units identified at the site comprise materials which are considered susceptible to liquefaction, as follows:

- Unit 3: Firm sandy SILT and SAND (approx. 0.8-1.2m thick) and,
- Unit 5: Loose Silty SAND and SAND interbedded with SILT and CLAY (4.0-8.5m thick).

⁵ New Zealand Standard NZ 1170.5:2004 Structural Design Actions: Part 5: Earthquake actions – New Zealand.

⁶ Geologismiki (2020), CPET-IT – detailed software package for the interpretation of Cone Penetration Test (CPTu) data.

It is noted that more cohesive layers, locally identified as part of this unit, are not considered susceptible to liquefaction, based on the laboratory Atterberg Limit test results. The Atterberg Limit tests carried out by Babbage Geotechnical Testing Laboratory (refer to Appendix D) show that these more cohesive layers have a Plasticity Index (PI) of over 14 and are therefore considered unlikely to liquefy according to the MBIE – Module 3⁷ guidelines.

Should the inferred soil behaviour type (I_c) of the soil layers tested with a PI > 12, shows these soils at the limit between clay-like and sand-like behaviour, the liquefaction analyses have been manually changed by reducing the soil behaviour cut-off value I_c from 2.6 previously adopted to 2.4-2.5, in order to model the non-susceptibility of these soils.

For the soils identified as susceptible to liquefaction, the liquefaction triggering assessment carried out using CLiq indicates the risk of liquefaction under SLS seismic event is low across the site (FoS > 1.0). For the ULS design event, the analysis indicates that liquefaction triggering may occur at various depth and thickness across the site. The liquefaction assessment results based on CPT data are attached in Appendix E and summarised in Table 6-2 below:

Table 6-2: Liquefaction Assessment Summary for ULS seismic event

Unit ID	Material Description	Identified potentially liquefiable zone			LSN	LPI
		Depth from (m)	Depth to (m)	Thickness (m)		
Unit 3	Firm sandy SILT and SAND	1.2-1.6	1.3-2.5	0.1-0.7	15-30	12-25
Unit 5	Loose Silty SAND and SAND interbedded with SILT and CLAY	3.0	10-11.8	0.1-2.5		

The general performance levels for liquefied deposits at the site are estimated in accordance with the MBIE-Module 3 guidelines, based on the review of the liquefaction severity number (LSN) and liquefaction potential (LPI) calculated for each CPT. The review of the LSN and LPI results indicates that the risk of liquefaction affecting the site is classified as 'High'.

According to the MBIE Module 3, liquefaction could result in transient lateral displacements, moderate differential movements and settlements of the ground in the order of 100mm-200mm. This range is in general accordance with the settlements estimated using the Zhang et al (2002) method. However, these settlements should be treated as proxy for damage only and do not reflect a reliable estimate of actual settlements. The predicted liquefaction induced settlement might lead to damage to the future building foundations and slabs. The Structural Engineer should allow for predicted liquefaction induced settlements in the design and/or for future repairs post-earthquake.

Additionally, although earthworks are currently undertaken at the site, to generally raise the overall site level by up to 1.2m, which will result in a non-liquefiable crust thickness varying between 1.5m and 2.0m, we do not recommend to rely on any beneficial effects from the non-liquefiable crust. The thickness of soil overlying potentially liquefiable layers is not considered as sufficiently reliable to mitigate the manifestation and damaging effects of liquefactions. The future buildings should be designed to accommodate for liquefaction damages. Recommended foundations at the site are presented in Section 6.6 of this report.

⁷ MBIE (2016), Earthquake Geotechnical Engineering Practise: Module 3: Identification, assessment, and mitigation of liquefaction hazards,

The old open channel located along the eastern site boundary has been infilled. The site finished ground is generally level without any open slope faces, and on this basis, risk of lateral spreading is considered to be negligible.

6.4 Static Settlement

The site is underlain by Holocene Alluvium deposits, which are considered susceptible to consolidation settlement. Settlement analyses have been undertaken to estimate primary consolidation settlements induced either a) by the earthworks fill placement (average 1.0m fill thickness) or b) by floor slab dead and live loads from future residential buildings.

Settlement analyses have been undertaken to estimate primary consolidation settlements from available CPT data using the geotechnical analysis software CPET-IT. A Boussinesq load distribution has been considered for the analyses.

6.4.1 Fill – Primary Consolidation Settlement

Primary consolidation settlement induced from earthworks have been estimated assuming 1.0m fill thickness placed across a 100 m by 100 m square area. A unit weight of 20kN/m³ has conservatively been adopted for the fill material.

The primary consolidation settlements estimated under 1.0m fill across the site range from 20mm-60mm across the site. Results output are presented in Appendix F.

The time for consolidation settlements to be completed is dependent on the soil composition, the compressible layer thicknesses and the extent of filling. Settlement monitoring after fill placement has been completed across the site. Installation of services, pavement, and construction of future buildings at the site would only take place after these consolidation settlements have occurred, which should be demonstrated by a stabilisation in readings.

Settlement monitoring results have been reviewed by the Geotechnical Designer to confirm the long-term settlements are not expected to be worse than those predicted. This is covered in section 6.4.3 below.

6.4.2 Building – Primary Consolidation Settlement

For the purposes of assessing post-construction settlement induced by future building loads, it has been assumed that any earthworks related consolidation settlements will be completed prior to construction starting.

Primary consolidation settlements induced by future building construction have been estimated for a typical 10kPa floor load across a 15m by 15m square area. Results output are presented in Appendix F.

The primary consolidation settlements under future building loads, based on CPT data, are estimated to be less than 25mm. Differential settlements in the order of 1 in 500 are generally expected considering the maximum total settlement value estimated.

The predicted total and differential settlements are understood to be typically tolerable for the proposed type of development, provided adequate foundation system are selected and designed to accommodate the predicted long-term settlements. Recommended foundations and/or ground improvement at the site are presented in Section 6.6 of this report.

6.4.3 Settlement Monitoring

The client instructed Zorn Surveying to install and monitor settlement pins installed on approximately every 3rd lot at the subdivision. This was to ensure that ground settlement due to the placement of fill at the site has ceased prior to construction of the dwelling.

The results of the settlement monitoring are attached in Appendix F. In summary, all the settlement pins recorded less than 10mm of settlement over a 4-week period.

6.5 Retaining wall parameters

It is proposed to construct a retaining wall along the western boundary of the proposed subdivision. This is to retain the land from the neighbouring sites due to the proposed filling earthworks that are being undertaken to meet the NCC Flood levels in the area.

The retaining wall has been designed by Stratagroup and Engineering approval has been granted by the Napier City Council for this.

Retaining wall design parameters are presented in Table 6-3 below. All retaining walls should be designed to accommodate future potential surcharge pressures (up to 12kPa for any future new dwelling on the site).

Table 6-3 - Retaining Wall Design Parameters

Geological Unit	Bulk Density (kN/m ³)	Young's Modulus of Elasticity E (mPa)	Strength		Earth Pressure Coefficients		
			Effective cohesion c' (kPa)	Friction angle, φ' (deg)	Active K _a	Passive K _p	At Rest K _o
Engineered Fill	19	20	0	30	0.285	4.288	0.50
Holocene Alluvium	18	10	2	28	0.309	3.868	0.53

6.6 Foundations for Lots 3 to 24 only

Given the presence of liquefiable soils at site, we consider that this risk to future buildings would be too high for standard shallow strip footing foundation option on the recently placed engineered fill. We consider that all dwellings to be located on Lots 3 to 24 are constructed on a gravel raft with an engineering raft type foundation. These foundation types are very common for residential type buildings in the Hawkes Bay due to their ability to withstand differential settlements in the event of an earthquake event. This option is outlined below:

Gravel Raft

We recommend that the existing ground be undercut by 600mm and backfilled with imported hardfill and compacted to form a gravel raft beneath the building platform. The horizontal extent of gravel raft should be at least 1.0m outside perimeter of the building.

The imported hardfill should be placed and compacted in maximum 200mm layers using a smooth drum roller. The supplier of the hardfill should provide a NZ Heavy Compaction curve for the material which indicates the Maximum Dry Density (MDD).

The following testing should be carried out to ensure adequate compaction is being achieved:

- 95 % of MDD
- Clegg Impact values (CIV) greater than 20

Testing should be carried on a 5m grid on every 2nd lift and on the final surface.

Two layers of geogrid should be placed at the base of the excavation and at the mid-height of the gravel raft.

Foundations

A structural raft foundation (rib raft or other property system) should be designed with the following bearing capacities:

- Geotechnical ultimate bearing capacity 300kPa
- ULS factored bearing capacity 150kPa
- Allowable bearing capacity 100kPa

A raft foundation also prevents the building from 'pulling apart' in a large earthquake.

7. Main Conclusions

The geotechnical investigations and completion reporting have established that the Stage 2 (Lots 3 to 24) of the Kenny Rd Subdivision, Te Awa, Napier is suitable for residential development in accordance with the recommendations outlined in this geotechnical completion report.

The main point is that all lots 2 to 24 require the installation of a 600mm gravel raft beneath the proposed dwelling footprint and that a structural raft foundation is constructed. We recommend that the Napier City Council adopt this recommendation when assessing individual Building Consent Applications for the site.

It should be noted that additional work will be required to backfill the existing stormwater detention pond within Lot 2. Initia will provide a letter report specifically for this lot when the work has been completed.

8. Applicability

This report has been prepared for our client, Greenstone Land Developments Ltd, with respect to the brief provided to us. We note that only a representative sample of earthworks were reviewed by Initia and therefore we are relying on the contractor's PS3 for compliance with design. No liability is accepted for any omissions represented by those documents. The contractors PS3 should be obtained by the client and submitted to NCC. The advice and recommendations presented in this report should not be applied to any other project or used in any other context without prior written approval from Initia Limited.

56 KENNY ROAD – PRELIMINARY GEOTECHNICAL REPORT

EXECUTIVE SUMMARY

The site comprises loose unconsolidated alluvial deposits, highly susceptible to liquefaction. Deep tree root bowls and rubbish holes may be encountered onsite.

Foundations will require TC3 type in accordance with MBIE Part C Technical Guidance, dated April 2015 which in Hawkes Bay, practically means a 1.2m undercut with reinforced (geogrid+geofabric), gravel raft fill.

The site has a very high risk of liquefaction with vertical settlements of 300mm anticipated for a ULS event. Lateral spread is possible on the eastern boundary (adjacent to the existing drain) and is a definite risk for any new drainage or excavations.

The site is prone to flood levels for a 50 year return period. Earthworks may be required to elevate ground level above flood levels.

Road subgrades are <3% and will require lime and cement modifications to achieve adequate subgrade.

The site has been assessed for the levels and ground conditions at the time of testing. Any changes to ground levels or excavations are likely to affect geotechnical recommendations and need to be specifically considered.

INTRODUCTION

Greenstone Land Development Ltd has engaged Resource Development Consultants Ltd (RDCL) to undertake a Preliminary Geotechnical Report at 56 Kenny Road, Te Awa Napier.

The findings in this report are based on current ground conditions and levels at the time of testing. Any changes in levels or ground conditions as a result of earthworks may have a significant impact on the geotechnical engineering and will need to be considered at that time.

SITE DESCRIPTION

The site is located at 56 Kenny Road, Te Awa ~90m from the coastline and is bordered by Erickson Road to the west, Kenny Road to the south and residential subdivision to the north and east.

The site is near level, with a man-made drainage channel (1m wide x 0.5m deep) oriented north to south along the eastern boundary.

A residential dwelling, garage and ancillary shed is located on the property adjacent to Kenny Road to the south-east.

The south eastern quadrant of the site is planted in citrus and large wind-break trees border the boundary.

SCOPE OF WORK

Our scope of work is presented in the short form agreement (SFA), reference 19290, dated 17 May 2019.

DESKTOP STUDY

GEOLOGY

The site subsoils are likely to comprise loose, unconsolidated estuarine, lagoon and swamp deposits of sand, silt and minor gravel that has been drained or reclaimed since 1850 (Hawkes Bay Emergency Management Group portal).

The HBEMP indicates no known faults cross the site (Hawkes Bay Emergency Management Group Portal).

LIQUEFACTION SUSCEPTIBILITY

The online Hawkes Bay Emergency Management Group Portal (HBEMP) indicates the site is located within a zone of “High Liquefaction vulnerability”.

HISTORICAL IMAGERY

Historical Imagery reviewed from RetroLens.NZ database since 1948 indicates the site comprised a residential dwelling on the corner of Erickson Road and Kenny Road and the land has been used as farmland. No significant earthworks or earthwork modifications were evident in the photos.

FLOODING

The HBEMG portal indicates the site is prone to flooding.

Based on that dataset, the Flood extents are:

- Flood Return Period 50 (yr);
- Site Contours ~11m to 11.5m (From NCC Intramaps database);
- Flood Level 11.3m (datum msl – 10m);
- Accuracy 0.2.

RUBBISH DUMPS

Anecdotal evidence (discussion with neighbour) suggests there may be a small buried rubbish hole or holes across the site. Rubbish may include household waste, organic waste, and contaminants.

CONTAMINATION

Contamination assessment is explicitly excluded from this work. We simply make the comment that the risk of contamination on this site does seem plausible.

SITE TESTING

RDCL undertook site testing on 21/5/2019 and consisted of the following:

- Eight (8) Test Pit excavations; to
 - Between 3m and 3.4m below ground level (depth of excavator).
- Eight (8) DCP tests undertaken within the test pit excavation: to
 - 2.9m depth, terminated at target depth.
- Ten (10) CPT Tests to between:
 - 10.34m and 13.42m, terminated due to high qc (~20MPa).

Test Pit Logs are in Appendix A with CPT test logs in Appendix B.

SITE INVESTIGATION RESULTS

SUBSOIL CONDITIONS

The shallow subsoil conditions typically comprised, horizontally bedded unconsolidated alluvial deposits consistent with the published geology. Typical sequence from testing is for:

- TOPSOIL (0.15m to 0.3m thick); Organic sandy SILT, dark brown moist with some rootlets; overlying
- SILT and f-m SAND (to 0.9m and 1.3m bgl): grey with orange mottling, loose, non to low-plastic, moist, trace of rootlets;
- Silty CLAY or clayey SILT, trace of sand (to 1.4m and 2.1m bgl); grey with orange mottling, wet, firm, moderate plasticity;
- F-m SAND (to 2.4m and 3.0m bgl), dark bluish grey, minor shells, wet, medium dense
- Silty CLAY to depth of excavations, some fine sand, bluish grey, wet, soft, moderate plasticity.

Sensitive fine grained materials were encountered within 2m depth in CPT tests indicated weak or soft clay or organic materials.

GROUNDWATER

Groundwater seepage was encountered between 2.3m and 2.9m depth. Groundwater is anticipated to fluctuate seasonally and could be anticipated to be encountered at shallow depths

GEOTECHNICAL ASSESSMENT

SHALLOW BEARING CAPACITY

DCP test results correlated to Ultimate Bearing Capacity (UBC) in accordance with M.J Stockwell (1977) indicate low bearing soils of:

- >200kPa UBC; which are
- Likely to reduce in bearing capacity when wet (i.e. after rain).

LIQUEFACTION ASSESSMENT

LIQUEFACTION POTENTIAL

A liquefaction assessment was carried out on the results of the CPT investigation (Appendix B). The assessment indicates the site is at:

- Very High risk of liquefaction (LPI) during an Ultimate Limit State (ULS) design seismic event, and
- High Risk of liquefaction during a Serviceability Limit State (SLS) with
 - Moderate to severe expression of liquefaction based on Liquefaction Severity Number (LSN).

Liquefaction assessment outputs are attached as Appendix C.

VERTICAL SETTLEMENT

Vertical settlement assessment is anticipated to be:

- ~200mm to 300mm under ULS conditions; and
- ~220mm under SLS conditions.

DIFFERENTIAL SETTLEMENT

Differential settlement is anticipated to be:

- ~150mm during a ULS event

LATERAL SPREAD

Lateral spreading on the eastern boundary into the shallow drain should be considered.

Any new excavations such as stormwater drainage trenches or the like, which would result in a free face into which lateral spread could develop, need to be carefully considered.

Engineering works to protect against lateral spread in that case would most likely be required.

BASIS OF ASSESSMENT

The liquefaction assessment for the site was carried out using CLiq, accepted industry software package, CPT data of current ground conditions and the following input parameters (NZS1170.5 section 3.1.3 (Standards New Zealand, 2004)):

- Magnitude (M) = 7.5 (SLS & ULS);
- PGA = 0.44 g (ULS), based on:
 - Z = 0.38 (Napier);
 - C = 1.12 (Class D Soil), and
 - R = 1 (ULS).
- Groundwater level assumed 1.0 m deep based on TP investigation.

The design earthquake was chosen on the basis of probability of recurrence. The probability is based on historical earthquakes. A 7.5 magnitude earthquake for an Importance Level 2 correlates with a 500 year return period (ULS). A 50 year design life was assigned.

The liquefaction analysis method used was Moss et al (2006).

SEISMIC SOIL CLASSIFICATION

The site is classified as site subsoil “Class D – Deep or Soft Soil Site” in accordance with NZS1170.5:2004, part 5: Earthquake Actions – New Zealand.

The site subsoil class was assessed based on review of borehole lithology in them surrounding area in Hawke’s Bay Regional Council (HBRC) Well Database.

GEOTECHNICAL CONSIDERATIONS

GROUND CONDITIONS

Ground conditions comprise loose, unconsolidated silts and sands of weak bearing and susceptible to liquefaction. Naturally occurring organic materials (peat, buried organics) may be encountered at shallow depth within 1m of ground level.

Relic root bowls may be encountered where old shelter belts once stood. These may be susceptible to low bearing and long term settlement.

FLOOD LEVEL EARTHWORKS

Ground levels are anticipated to be required to be increased above the existing flood levels (+0.2m) plus freeboard. Fill materials on site are unlikely to be suitable for structural fill in the natural state. Fill will most likely need to be imported, or site materials stabilised with cement.

Site testing of source material will be required to understand the classification and compaction criteria. All fill work would need to be under direction and approval of a chartered geotechnical engineer.

ANTICIPATED FOUNDATIONS

Conditions do not meet the requirements of NZS3604:2011 due to liquefaction and low bearing capacity. Specific design will be required for all foundations.

Liquefaction criteria determine that foundations will require:

- TC3 Type in accordance with MBIE Part C Technical Guidance, version 3a, dated April 2015.

Practically, in Hawkes Bay, this means a 1.2m deep undercut with reinforced (geogrid + geofabric), gravel raft fill.

ROAD SURFACING

Insitu subgrade comprises weak, alluvial soils with low subgrade strengths (CBR of <3%). Ground improvement may be required to achieve suitable subgrade capacity.

Earthworks to treat flood level may incorporate engineered fill to improve road subgrade CBR and may require lime cement modification.

BURIED RUBBISH AND TREE HOLES

There may be a risk that buried rubbish and tree holes may be exposed during topsoil stripping. If encountered these will need to be excavated to the full depth and reinstated with engineered fill.

LIMITATIONS

- This letter has been prepared for the particular purpose outlined in the project brief and no responsibility is accepted for the use of any part in other contexts or for any other purpose.
- Ground conditions assessed in this letter are inferred from published sources, site inspection and the investigations described. Variations from the interpreted conditions may occur, and special conditions relating to the site may not have been revealed by this investigation, and which are therefore not taken into account. No warranty is included either expressed or implied that the actual conditions will conform to the interpretation contained in this letter.
- No responsibility is accepted by Resource Development Consultants Ltd for inaccuracies in data supplied by others. Where data has been supplied by others, it has been assumed that this information is correct.
- Groundwater conditions can vary with season or due to other events. Any comments on groundwater conditions are based on observations at the time.
- This letter is provided for sole use by the client and Napier City Council and is confidential to the client and their professional advisors. No responsibility whatsoever for the contents of this letter shall be accepted for any person other than the client.

We trust this meets your current needs. Should you wish to discuss any aspect of the contents of this document please contact me the undersigned on 06 877 1652.

Sincerely,

Prepared by:

2	Clay - organic soil	7	Dense sand to gravelly sand
3	Clays: clay to silty clay	8	Stiff sand to clayey sand
4	Silt mixtures: clayey silt & silty clay	9	Stiff fine-grained

Notes & Limitations

Data shown on this report has been assessed to provide a basic interpretation in terms of Soil Behaviour Type (SBT) and various geotechnical soil and design parameters using methods published in P. K. Robertson and K.L. Cabal (2010), Guide to Cone Penetration Testing for Geotechnical Engineering, 4th Edition. The interpretations are presented only as a guide for geotechnical use, and should be carefully reviewed by the user. Geric Solutions Ltd do not warranty the correctness or the applicability of any of the geotechnical soil and design parameters shown and does not assume any liability for any use of the results in any design or review. The user should be fully aware of the techniques and limitations of any method used to derive data shown in this report.

The figure displays a Soil Behaviour Type (SBT) log from a CPT test. The vertical axis represents the depth or scale, ranging from 1 to 14. The horizontal axes show raw data (Tip Resistance, Friction Ratio, Pore Pressure) and estimated parameters (Dr, Su, N60).

- Raw Data:**
 - Tip Resistance (MPa):** Red line, increasing with depth.
 - Friction Ratio (%):** Green line, generally decreasing with depth.
 - Pore Pressure (kPa):** Cyan line, showing a significant increase starting around scale 10.
- Estimated Parameters:**
 - Dr (%)**: Depth resistance, plotted as a dashed blue line.
 - Su (kPa)**: Undrained shear strength, plotted as a solid blue line.
 - N₆₀**: SPT N-value, plotted as a solid red line.
- Soil Behaviour Type (SBT) Classification:** The log shows the following soil types based on SBT:
 - 0-1: Sand mixtures: silty sand to sandy silt
 - 1-2: Clays: clay to silty clay
 - 2-3: Clays: clay to silty clay
 - 3-4: Sand mixtures: silty sand to sandy silt
 - 4-5: Clays: clay to silty clay
 - 5-6: Clays: clay to silty clay
 - 6-7: Clays: clay to silty clay
 - 7-8: Sand mixtures: silty sand to sandy silt / Silt mixtures: clayey silt & silty clay
 - 8-9: Clays: clay to silty clay
 - 9-10: Sand mixtures: silty sand to sandy silt / Sand mixtures: silty sand to sandy silt
 - 10-11: Clays: clay to silty clay
 - 11-12: Clays: clay to silty clay
 - 12-13: Silt mixtures: clayey silt & silty clay
 - 13-14: Sands: clean sands to silty sands

LIQUEFACTION ANALYSIS REPORT

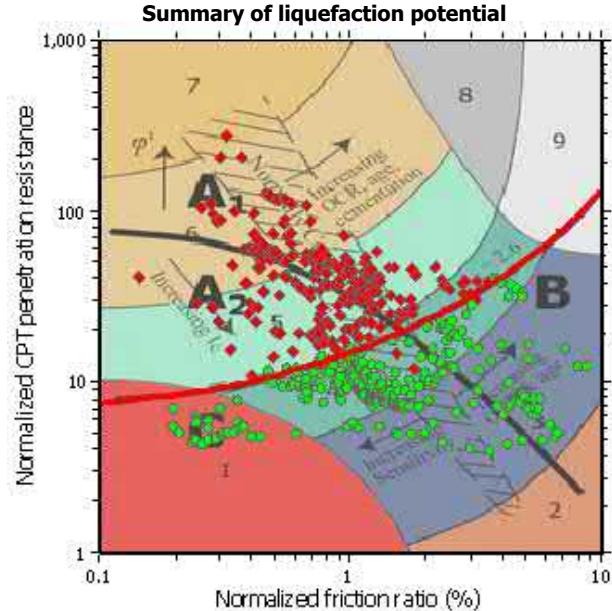

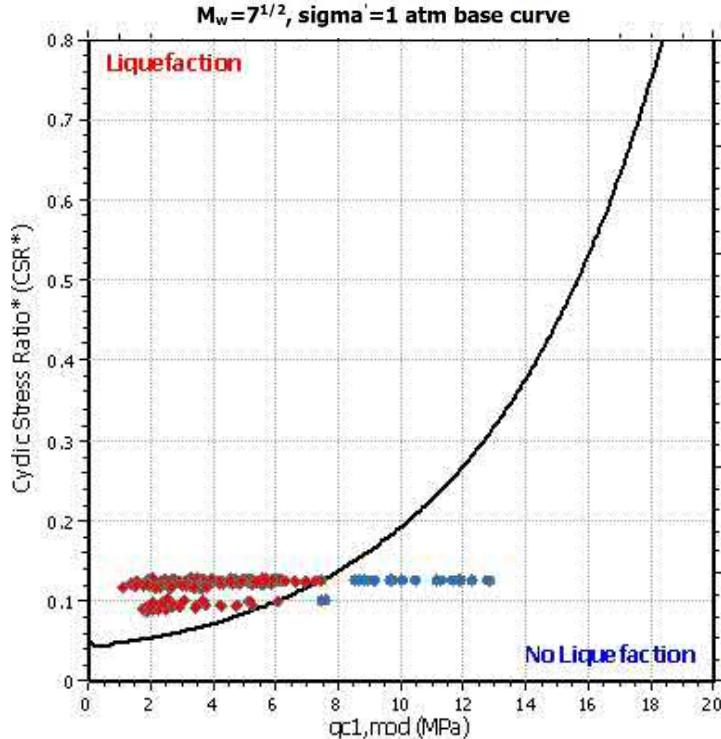

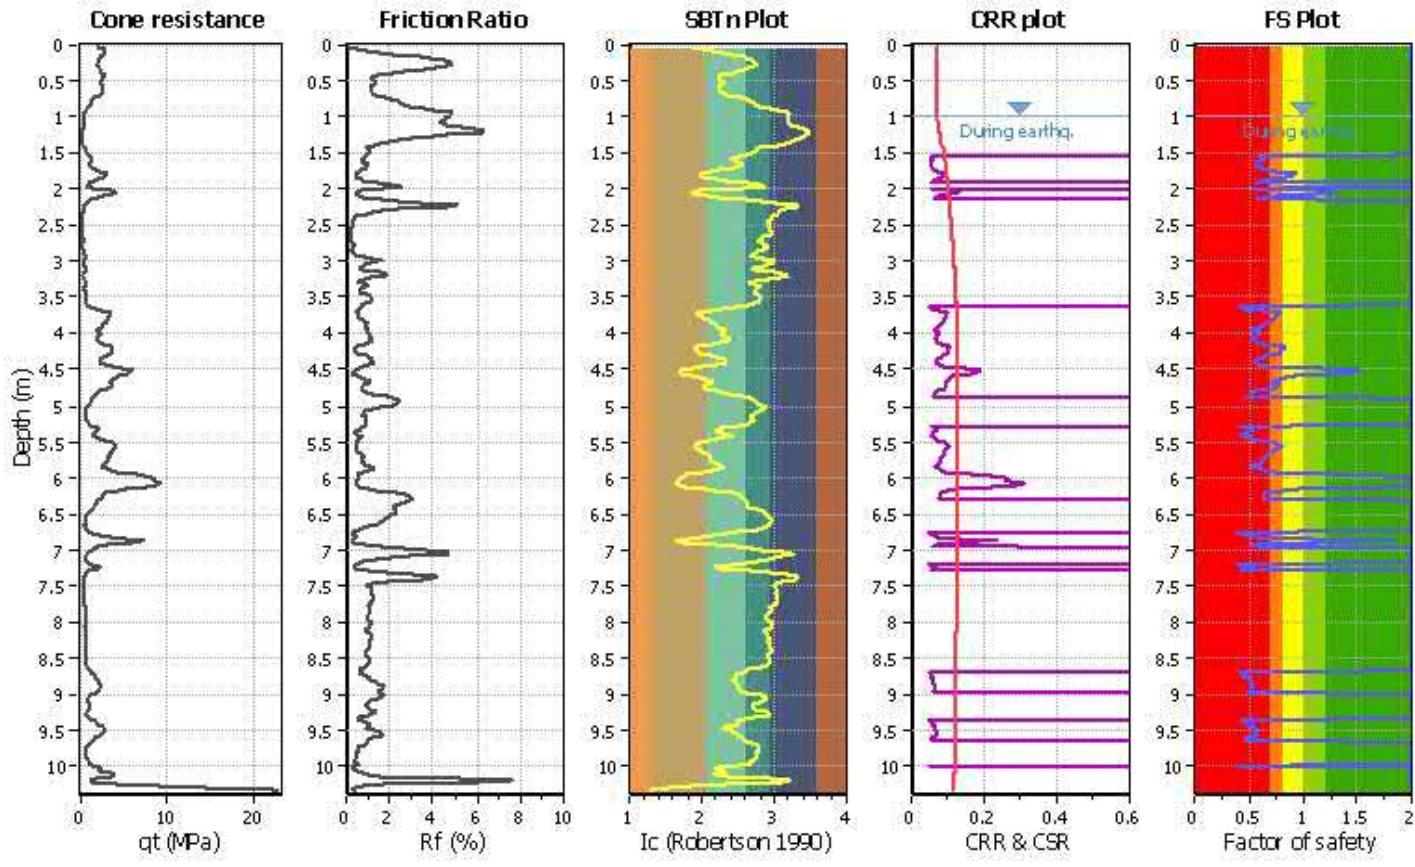

Project title :

Location :

CPT file : CPT01 SLS

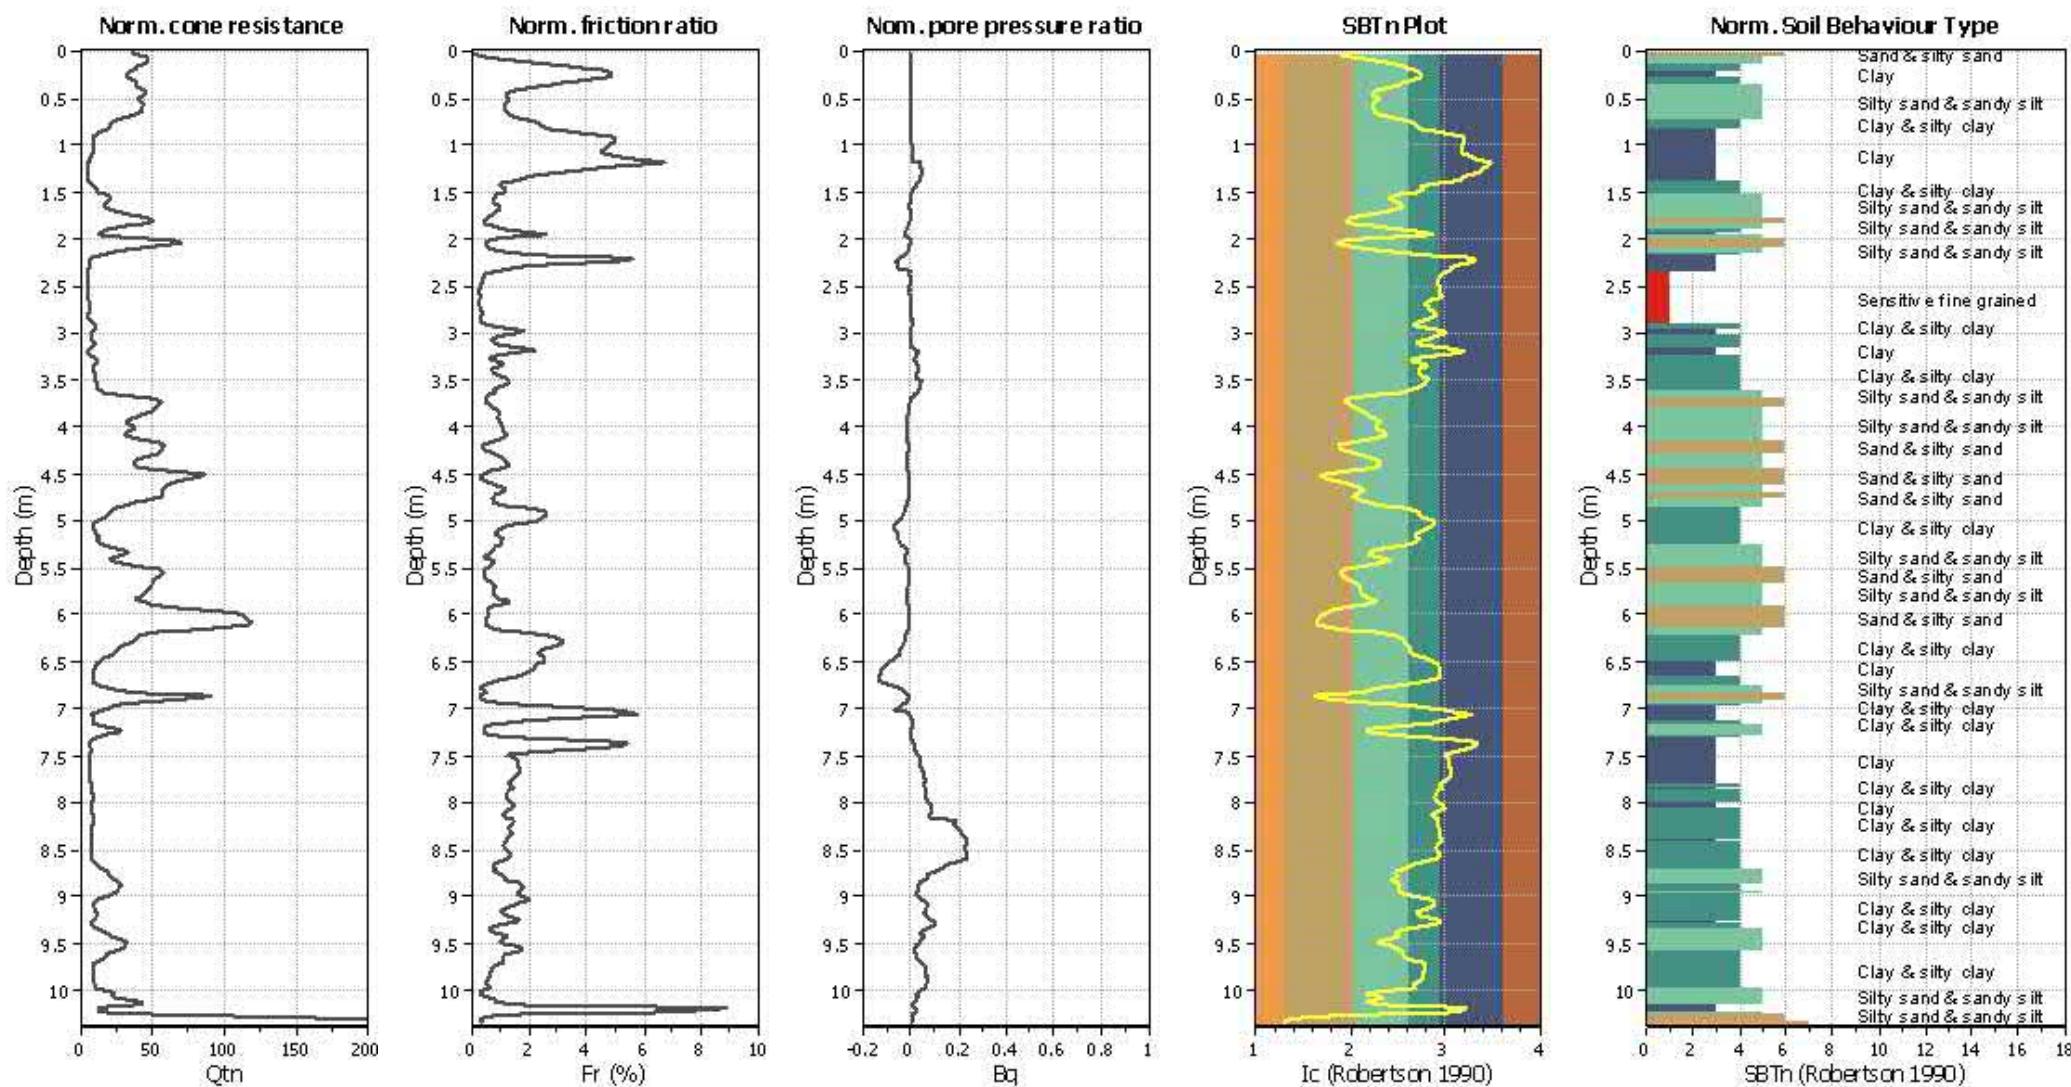

Input parameters and analysis data

Analysis method:	Moss et al. (2006)	G.W.T. (in-situ):	2.00 m	Use fill:	No	Clay like behavior applied:	Sands only
Fines correction method:	Moss et al. (2006)	G.W.T. (earthq.):	1.00 m	Fill height:	N/A	Limit depth applied:	Yes
Points to test:	Based on Ic value	Average results interval:	3	Fill weight:	N/A	Limit depth:	10.00 m
Earthquake magnitude M_w :	7.50	Ic cut-off value:	2.60	Trans. detect. applied:	No	MSF method:	Method based
Peak ground acceleration:	0.11	Unit weight calculation:	Based on SBT	K_0 applied:	Yes		

Zone A₁: Cyclic liquefaction likely depending on size and duration of cyclic loading
Zone A₂: Cyclic liquefaction and strength loss likely depending on loading and ground geometry
Zone B: Liquefaction and post-earthquake strength loss unlikely, check cyclic softening
Zone C: Cyclic liquefaction and strength loss possible depending on soil plasticity, brittleness/sensitivity, strain to peak undrained strength and ground geometry

CPT basic interpretation plots (normaliz

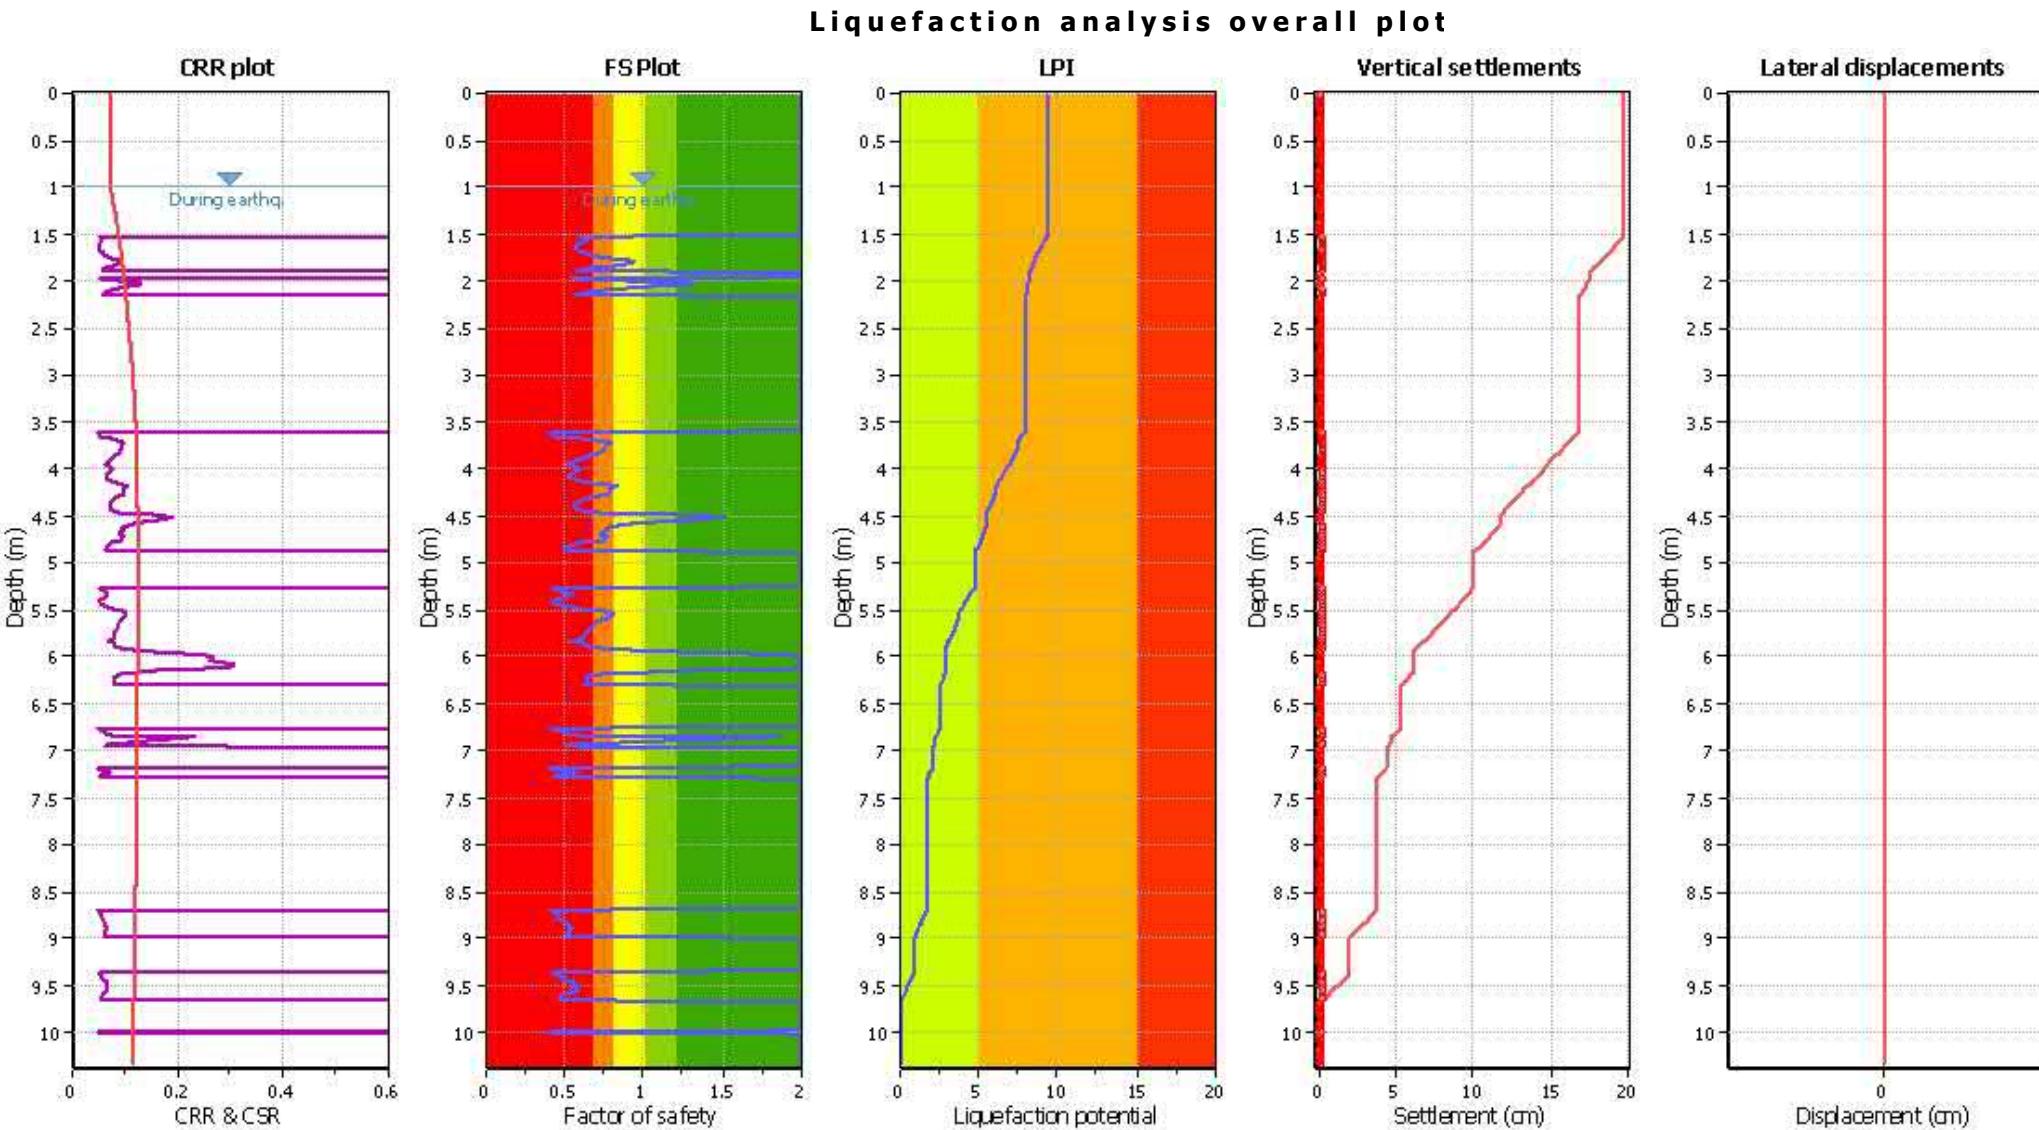

Input parameters and analysis data

Analysis method: I&B (2008)
 Fines correction method: R&W (1998)
 Points to test: Based on Ic value
 Earthquake magnitude M_w : 7.50
 Peak ground acceleration: 0.11
 Depth to water table (in situ): 2.00 m

Depth to GWT (erthq.): 1.00 m
 Average results interval: 3
 Ic cut-off value: 2.60
 Unit weight calculation: Based on SBT
 Use fill: No
 Fill height: N/A

Fill weight:
 Transition detect. applied: No
 K_0 applied: Yes
 Clay like behavior applied: Sands only
 Limit depth applied: Yes
 Limit depth: 10.00 m

SBTn legend

Important Information about This Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, clients can benefit from a lowered exposure to the subsurface problems that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed below, contact your GBA-member geotechnical engineer. Active involvement in the Geoprofessional Business Association exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Geotechnical-Engineering Services Are Performed for Specific Purposes, Persons, and Projects

Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical-engineering study conducted for a given civil engineer will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared solely for the client. *Those who rely on a geotechnical-engineering report prepared for a different client can be seriously misled.* No one except authorized client representatives should rely on this geotechnical-engineering report without first conferring with the geotechnical engineer who prepared it. *And no one – not even you – should apply this report for any purpose or project except the one originally contemplated.*

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read it *in its entirety*. Do not rely on an executive summary. Do not read selected elements only. *Read this report in full.*

You Need to Inform Your Geotechnical Engineer about Change

Your geotechnical engineer considered unique, project-specific factors when designing the study behind this report and developing the confirmation-dependent recommendations the report conveys. A few typical factors include:

- the client's goals, objectives, budget, schedule, and risk-management preferences;
- the general nature of the structure involved, its size, configuration, and performance criteria;
- the structure's location and orientation on the site; and
- other planned or existing site improvements, such as retaining walls, access roads, parking lots, and underground utilities.

Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light-industrial plant to a refrigerated warehouse;
- the elevation, configuration, location, orientation, or weight of the proposed structure;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project changes – even minor ones – and request an assessment of their impact. *The geotechnical engineer who prepared this report cannot accept responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.*

This Report May Not Be Reliable

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, that it could be unwise to rely on a geotechnical-engineering report whose reliability may have been affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If your geotechnical engineer has not indicated an "apply-by" date on the report, ask what it should be, and, in general, if you are the least bit uncertain about the continued reliability of this report, contact your geotechnical engineer before applying it.* A minor amount of additional testing or analysis – if any is required at all – could prevent major problems.

Most of the “Findings” Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site's subsurface through various sampling and testing procedures.

Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing were performed. The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgment to form opinions about subsurface conditions throughout the site. Actual sitewide-subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team from project start to project finish, so the individual can provide informed guidance quickly, whenever needed.

This Report's Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, *they are not final*, because the geotechnical engineer who developed them relied heavily on judgment and opinion to do so. Your geotechnical engineer can finalize the recommendations *only after observing actual subsurface conditions* revealed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. *The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.*

This Report Could Be Misinterpreted

Other design professionals' misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a full-time member of the design team, to:

- confer with other design-team members,
- help develop specifications,
- review pertinent elements of other design professionals' plans and specifications, and
- be on hand quickly whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction observation.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, *but be certain to note conspicuously that you've included the material for informational purposes only*. To avoid misunderstanding, you may also want to note that "informational purposes" means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report, but they may rely on the factual data relative to the specific times, locations, and depths/elevations referenced. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, *only* from the design drawings and specifications. Remind constructors that they may

perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled "limitations," many of these provisions indicate where geotechnical engineers' responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a "phase-one" or "phase-two" environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually relate any environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated subsurface environmental problems have led to project failures.* If you have not yet obtained your own environmental information, ask your geotechnical consultant for risk-management guidance. As a general rule, *do not rely on an environmental report prepared for a different client, site, or project, or that is more than six months old.*

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, none of the engineer's services were designed, conducted, or intended to prevent uncontrolled migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, *proper implementation of the geotechnical engineer's recommendations will not of itself be sufficient to prevent moisture infiltration.* Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. *Geotechnical engineers are not building-envelope or mold specialists.*

Total depth: 13.92 m

Analysis method: B&I (2014)
Fines correction method: B&I (2014)
Points to test: Based on Ic value
Earthquake magnitude M_w : 6.90
Peak ground acceleration: 0.33

G.W.T. (in-situ): 1.00 m
G.W.T. (earthq.): 1.20 m
Average results interval: 3
Ic cut-off value: 2.50
Unit weight calculation: Based on SBT

Use fill: No
Fill height: N/A
Fill weight: N/A
Trans. detect. applied: No
 K_0 applied: Yes
Clay like behavior applied:
Limit depth applied: No
Limit depth: N/A
MSF method: Method based
